提要:【研究目的】滇东地区是中国南方重要的煤炭生产基地, 研究典型煤矿区小流域沉积物重金属来源及生态风险, 对煤矿区生态环境保护和治理有着重要的现实意义。【研究方法】系统采集小流域表层沉积物样品, 测定重金属 As、Cd、Cu、Pb、Hg、Mn、Ni、Cr、Zn 和 V 的含量, 运用地累积指数法、潜在风险指数法对重金属污染状况和潜在生态风险进行评价, 并通过数理统计方法分析了其潜在来源。【研究结果】小流域沉积物中除 As 和 Pb 外, 其余重金属均超过了云南省土壤背景值, 但仅 Cu 的平均含量超过风险筛选值。在空间分布上, Cr、Ni 和 V 为中等变异, 其余重金属为高度变异。各重金属污染程度排序为 Cr > Cu > Cd > Mn > Zn > V > Ni > Hg > Pb > As, 其中 Cr 主要为偏中度污染, Cu、Cd、Mn、Zn、V 和 Ni 主要为轻度污染, As、Pb 和 Hg 主要为无污染。沉积物重金属潜在生态风险总体呈低风险—中等风险, Cd 和 Hg 是最主要生态风险因子, 均表现为中等风险, 其余重金属的生态风险则较低。相关性分析、主成分分析和聚类分析结果表明, 沉积物重金属受到人类活动和自然背景的双重控制, 其中 Mn、Ni、V 和 Cr 主要为自然来源, As、Hg、Cd 和 Pb 主要为人为来源, 而 Cu 和 Zn 则受到自然来源和人为来源的综合影响。【结论】虽然研究区为滇东典型的地质高背景区, 但煤炭工业等人类活动对流域沉积物生态环境质量造成的潜在风险也不可忽视, 尤其要注意 Cd 和 Hg 的监测和治理。

关 键 词: 煤矿区; 小流域; 沉积物; 重金属; 来源; 风险评价; 环境地质调查工程; 云南

创 新 点:(1)深化了对滇东典型煤矿区小流域沉积物重金属污染特征及潜在生态风险的认识;(2)综合运用相关分析、主成分分析和聚类分析等数理统计方法, 明确了不同重金属的来源, 为滇东煤矿区沉积物重金属的有效防治提供了依据。

Abstract: This paper is the result of environmental geological survey engineering.

[Objective] Eastern Yunnan is an important coal base in southern China. To reveal the sources and ecological risks of heavy metals in sediments of small watersheds in typical coal mining areas is of great significance for the protection and treatment of ecological environment in coal mining areas. **[Methods]** The surface sediment samples were collected from small watersheds, and total contents of As, Cd, Cu, Pb, Hg, Mn, Ni, Cr, Zn and V were determined. The pollution degree and potential ecological risk of the heavy metals were evaluated by the geo-accumulation index and potential risk index, and their potential sources were analyzed based on mathematical statistics method. **[Results]** The results shows that the heavy metals in the sediments of small watershed exceed the soil background value of Yunnan Province except As and Pb, but only the average content of Cu exceed the risk screening value. In terms of spatial distribution, Cr, Ni and V are of medium variation while the other heavy metals are of highly variation. The pollution degree of each heavy metal can be ranked as Cr > Cu > Cd > Mn > Zn > V > Ni > Hg > Pb > As, in which the pollution of Cr is of moderate degree, the pollution of Cu, Cd, Mn, Zn, V and Ni are of mild degree, and the pollution of As, Pb and Hg are clean and pollution-free. The potential ecological risk of heavy metals in sediments presents a low risk to medium risk. Cd and Hg are the main ecological risk factors, showing moderate risk, while the ecological risk of other heavy metals is relatively low. The results of correlation analysis, principal component analysis and cluster analysis show that the contents of heavy metals in sediments are controlled by human activities and natural background, in which Mn, Ni, V and Cr are mainly from natural sources, As, Hg, Cd and Pb are mainly from man-made sources, and Cu and Zn are comprehensively affected by both of natural and man-made sources. **[Conclusions]** Although the study area is a typical geological high background area in eastern Yunnan, the potential risks caused by human activities such as coal industry to the ecological environment quality of sediments in the basin cannot be ignored, especially the monitoring and treatment of Cd and Hg.

Key words: coal mining area; small watershed; sediment; heavy metals; sources; risk assessment; environmental geological survey engineering; Yunnan Province

Highlights: (1) Providing a better understanding of heavy metal pollution characteristics and potential ecological risks in sediments of small watersheds in typical coal mining areas in eastern Yunnan; (2) By using mathematical statistical methods such as correlation analysis, principal component analysis and cluster analysis, we clarified the sources of different heavy metals, and provided a basis for the effective prevention and control of heavy metals in sediments of coal mining area in eastern Yunnan.

1 引言

重金属广泛存在于水体、土壤、沉积物等环境介质中，并可通过食物链进入人体并富集，进而危害人体健康(Cheng et al., 2014; 王丽等, 2015)。其来源除岩石、土壤的风化侵蚀外，还受工农业生产和社会等影响(马明真等, 2019)。水体中重金属具有难降解、持久性强和不可逆等特点，容易在沉积

物中富集，而当水环境发生改变时，沉积物重金属又会重新释放进入水体，对水体造成“二次污染”(于霞等, 2015; Feng et al., 2017)。同时，沉积物作为生态系统的重要组成部分及底栖生物的营养来源，其质量的下降也将会影响底栖生物的代谢和生存(Wang et al., 2014; You et al., 2016)。因此，研究流域沉积物重金属分布特征、污染状况和潜在生态风险，对流域人类健康和水生态系统具有重要意义。

中国是重要的煤炭生产和消费大国,遍布许多重要的煤炭生产基地和矿业型城市。矿业活动在促进经济发展的同时,也造成了严重的河流、土壤和大气等重金属污染问题(刘硕等,2016;贾亚琪等,2016;Yang et al., 2018;蔡永兵等,2021)。有研究指出,煤矿区重金属的来源主要有煤矸石的风化淋滤、矿山废水的排放和煤粉尘飘散迁移等(李红霞,2020),煤矿开采过后往往残存着多种重金属元素,常见的有As、Cd、Cr、Pb、Cu、Zn和Hg等(Jiang et al., 2017),而滇黔地区煤矿周边土壤和沉积物中常见的重金属污染元素主要为As、Cd和Hg等(庞文品等,2016;吴先亮等,2018;蔡敬怡等,2019)。

目前,国内外常用的水体沉积物重金属污染风险评价方法有地累积指数法、沉积物富集系数法、沉积物质量基准法、潜在生态风险指数法、污染负荷指数法和尼梅罗综合指数法等(陈明等,2015),其中潜在生态风险指数法考虑了重金属的生物毒理学和生态学内容,能直观反映重金属的生态和环境风险,在土壤和沉积物重金属的污染评价中备受关注(肖冬冬等,2017;周艳等,2018;张丽等,2020;尹德超等,2022)。在实际应用中通常会将几种评价方法结合使用,如张丽等(2020)的研究综合运用内梅罗综合污染指数法和潜在生态风险指数法评价了滇东南四个县的农田土壤重金属污染风险。尹德超等(2022)的研究通过地累积指数法和潜在生态风险指数法评价了雄安新区白洋淀表层沉积物重金属污染风险等。通过多种评价方法的结合,能够更加全面地评价重金属的污染状况(李保杰等,2018),为研究区河流水生态的保护和治理提供更准确的依据。

滇东地区是中国南方的煤炭富集区和煤炭生产基地,也是重要的煤层气勘探开发区,其煤炭开采已经有数十年的历史。前人从聚煤环境(罗忠等,2008;汪浩,2011)、煤岩特征(郑雪,2018;张平等,2019)、地应力分布(鞠玮等,2020)、煤层气富集(康永尚等,2018)及开发条件(姜杉钰等,2018)等方面,对滇东不同煤矿区进行了较为详尽的研究,但对煤矿区水土环境的关注则相对较少,且多是从区域角度进行分析。如熊燕等(2017)评价了南盘江流域(云南段)水系沉积物重金属含量分布特征及其污染状况,刘娟等(2021)研究关注了滇东6个

市(州)农田土壤铅污染特征及健康风险,涂春霖等(2021)对煤矿区地表水和地下水化学演化特征进行了报道,但对典型煤矿区小流域沉积物重金属的污染状况和生态风险还缺少系统的分析。为进一步深化滇东煤矿区水生态环境的研究,服务于煤矿集中区的环境保护和修复,本文以滇东典型煤矿区小流域为例,系统采集表层沉积物样品,分析沉积物重金属的空间分布特征和污染物来源,评估沉积物重金属污染状况和潜在生态风险,以期为滇东地区煤矿开采的环境影响评估和综合治理提供一定的参考。

2 材料与方法

2.1 研究区概况

研究区位于云南省富源县中部,是滇黔重要的煤炭生产基地之一,已有20多年的开采历史。小流域属珠江源区南盘江下游河段,汇水面积404 km²,在营上镇一带注入块择河。流域总体地势西南高而东北低,高程1575~2698 m,河水总体向北东径流。区内属亚热带季风气候,多年平均气温13.8℃,多年平均降雨量1177~1400 mm,降雨主要集中在每年6—9月,占全年降雨的55%以上。

流域内出露地层有二叠系栖霞—茅口组(P_1q-m)、峨眉山玄武岩(P_β)、宣威组(P_x),三叠系飞仙关组(T_f)、永宁镇组(T_{yn})和关岭组(T_g)等(图1)。其中宣威组(P_x)为煤系地层,分布面积28.75 km²,为主要的开采层位,含煤18~73层,其中可采煤层有8~20层,可采总厚度10~31 m(康永尚,2018)。区内煤矿资源丰富,矿业活动频繁,目前有大小煤矿山40余个,除部分还在生产外,多数已相继关闭。有煤矸石堆60余处,多沿沟谷分布,规模大小不等。在几十年的开采过程中,采煤和洗煤废水、煤矸石淋滤水和采煤粉尘等通过各种途径进入地表水体,进而可能在沉积物中积累和富集,但其污染状况和生态风险还缺少相关的研究。

2.2 样品采集与测试

2020年6—7月,在研究区布设37个沉积物采样点,基本覆盖了整个小流域,煤矿生产生活区和煤矸石堆上下游加密布样,采样点位置如图1所示。沉积物尽量在河流的中间地点采集,如沉积物较少难以采集,则在近岸水流滞缓处采集。使用抓

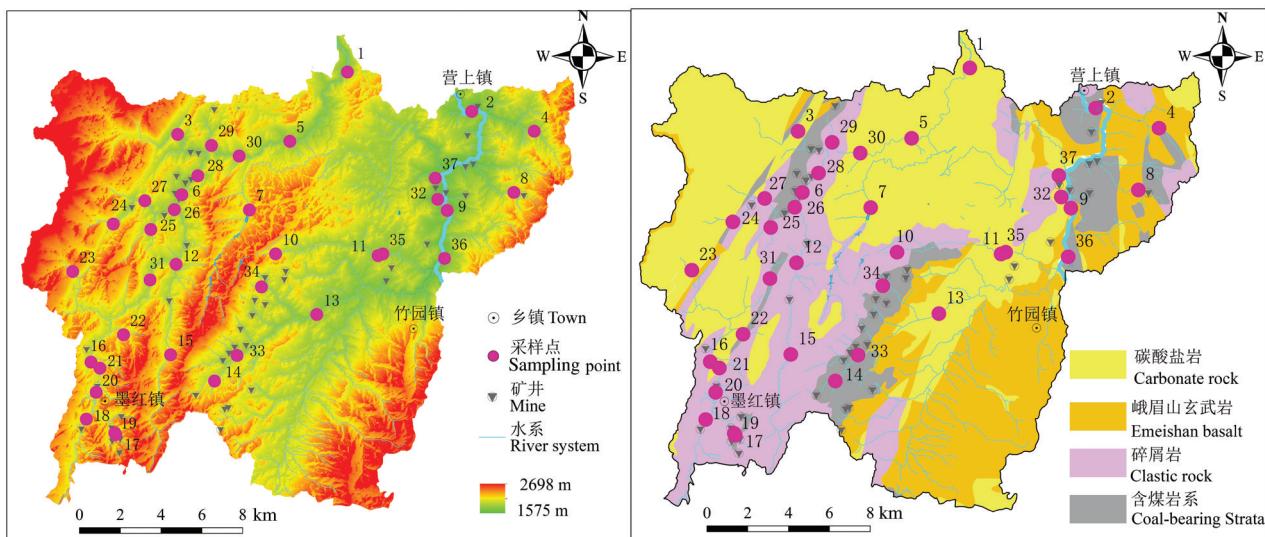

图1 滇东典型煤矿区小流域采样点分布示意

Fig.1 Location and distribution of sampling points in small watersheds in typical coal mining areas of Eastern Yunnan

泥斗采集0~10 cm 沉积物样品，并用自封袋密封，经室温风干后，剔除植物残体和碎石块等，研磨过100目筛，保存于塑料瓶中，送中国地质调查局昆明自然资源综合调查中心实验室进行检测。其中V、Ni、Mn和Zn用电感耦合等离子体发射光谱法测定，Cd、Pb和Cu用电感耦合等离子体质谱法测定，As和Hg用原子荧光光谱仪法测定，Cr用波长色散X射线荧光光谱法测定。元素的分析采用重复样以及国家一级标准物质进行质量监控，分析数据的报出率、准确度和精密度合格率均达到100%，满足相关规范要求。

2.3 评价方法

2.3.1 地累积指数法

地积累指数法是一种研究沉积物中重金属污染程度的定量指标，用以反映外源重金属在沉积物中的富集程度（张兆永等，2015；吴先亮等，2018；邬光海，2020）。其公式如下：

$$I_{geo} = \log_2[C_i/(1.5 \times B_i)] \quad (1)$$

式中， I_{geo} 为地累积指数， C_i 是指元素*i*在沉积物中的含量(mg/kg)，1.5是考虑到成岩作用可能会引起背景值的变动而取的系数， B_i 为该元素的地球化学背景值(mg/kg)，本次研究采用云南省土壤各元素背景值的算术平均值(1990)为参考值，根据地累积指数 I_{geo} 计算结果可将重金属污染程度划分等级如表1所示。

表1 重金属污染级别

Table 1 Heavy metal contamination levels

| I_{geo} | 分级 | 污染程度 |
|-----------|----|-------|
| <0 | 0 | 无污染 |
| 0~1 | 1 | 轻度污染 |
| 1~2 | 2 | 偏中度污染 |
| 2~3 | 3 | 中度污染 |
| 3~4 | 4 | 偏重度污染 |
| 4~5 | 5 | 重度污染 |
| >5 | 6 | 严重污染 |

2.3.2 潜在风险指数法

瑞典学者 Hakanson(1980)提出潜在风险指数法，该方法综合考虑了沉积物重金属的种类、含量、环境背景值及其毒性水平的协同作用，通过设定毒性响应系数对重金属进行综合评估，被国内外学者广泛用于评价沉积物中重金属的潜在生态风险（于霞等，2015；鲍丽然等，2020；李星渝等，2022）。其公式如下：

$$RI = \sum_i^M E_r^i = \sum_i^M T_r^i \times C_r^i = \sum_i^M T_r^i \times \frac{C_s^i}{C_n^i} \quad (2)$$

式中， RI 为沉积物重金属潜在生态风险指数， E_r^i 为单因子危害指数， T_r^i 为毒性响应系数，可以综合反映重金属的毒性、污染水平和污染的敏感程度（张兆永等，2015）。根据已有研究，重金属As、Cd、Cu、Pb、Hg、Mn、Ni、Cr、Zn和V的毒性响应系数分别为10、30、5、40、1、5、2、1和2（孙厚云等，

表2 潜在生态风险评估指标与等级划分

Table 2 Potential ecological risk assessment indicators and classification

| E_r^i | 危害程度 | RI | 危害程度 |
|------------------------|------|---------------------|------|
| $E_r^i < 40$ | 低 | $RI < 150$ | 低 |
| $40 \leq E_r^i < 80$ | 中 | $150 \leq RI < 300$ | 中 |
| $80 \leq E_r^i < 160$ | 强 | $300 \leq RI < 600$ | 强 |
| $160 \leq E_r^i < 320$ | 很强 | $RI \geq 600$ | 很强 |
| $E_r^i \geq 320$ | 严重 | / | / |

2021)。 C_r^i 为第 i 种重金属的污染系数, C_s^i 为污染物实测值(mg/kg), C_n^i 为被测元素的环境背景值(mg/kg), 本研究采用云南省土壤各元素背景值的算术平均值(1990)为参考值。根据 RI 和 E_r^i 值的大小, 潜在生态风险指数划分标准见表2。

2.4 数据处理

本研究数据采用 Excel 2016 进行处理和统计分析, 利用 SPSS19.0 进行 Pearson 相关分析、主成分分析和聚类分析, 采用软件 MapGIS6.7 和 ArcGIS 10.7 制作图件, 并用 Coreldraw X7 进行清绘。

3 结果与讨论

3.1 沉积物重金属含量变化特征

工作区沉积物重金属含量统计特征见表3。重金属 As、Cd、Cu、Pb、Hg、Mn、Ni、Cr、Zn 和 V 的平均值(mg/kg)分别为 15.42、0.51、118.88、25.99、0.08、1302.43、67.78、206.73、165.39 和 265.08, 含量依次排列为 $\text{Mn} > \text{V} > \text{Cr} > \text{Zn} > \text{Cu} > \text{Ni} > \text{Pb} > \text{As} > \text{Cd} > \text{Hg}$, 与云南省土壤背景值的比值分别为 0.84、2.34、2.57、0.64、1.32、2.08、1.59、3.17、1.84 和 1.71, 除 As 和 Pb 外, 其余重金属均超过了云南省土壤背景值。所有

采样点中 Cr 均超过了背景值, 92%~97% 的采样点中 Cd、Cu、Mn、Ni、Cr、Zn 和 V 含量超出背景值, 表明研究区河流沉积物中重金属的聚集趋势较为明显。总体来看, 除 Cu 外, 各重金属含量均值均低于风险筛选值, 表明沉积物的污染风险较低, 但也有部分点位超过风险筛选值, 需引起注意。Cu 含量为 34.2~398 mg/kg , 均值为 118.88 mg/kg , 其中 67.57% 的点位超过了风险筛选值。

变异系数(C_v)能反映沉积物中重金属区域分布的变异程度, 其值越大, 表明人类活动对重金属影响越高。各重金属变异系数大小依次为 $\text{As} > \text{Hg} > \text{Cd} > \text{Pb} > \text{Zn} > \text{Cu} > \text{Mn} > \text{Cr} > \text{Ni} > \text{V}$, 根据变异程度的分类(张兆永等, 2015; 温泉等, 2020), 重金属 Cr、Ni 和 V 变异系数分别为 33.37%、28.26% 和 26.79%, 为中等变异($15\% < C_v < 36\%$), 在流域内分布较均匀, 受人类活动影响较小; As、Hg、Cd、Pb、Zn、Cu 和 Mn 变异系数分别为 135.61%、94.79%、90.18%、72.23%、54.88%、49.59% 和 46.05%, 为高度变异($C_v > 36\%$), 在流域内分布不均匀, 空间差异性显著, 受人类活动影响较大。

工作区沉积物重金属含量总体高于中国全国水系和南方水系沉积物均值, 与当地表层土壤均值相近, 其中 As、Pb、Hg、Mn 和 Zn 含量略高于当地表层土壤, Cd、Cu、Ni、Cr 和 V 略低于当地表层土壤(表4)。但与西江上游有色金属矿区和南盘江流域(云南段)相比, 重金属 As、Cd、Pb、Hg 和 Zn 含量均较低, 而 Cu、Ni 和 Cr 较高, 这可能与地质背景和不同人类活动有关。与南盘江未受污染的单一岩性小流域沉积物相比(瞿书逸, 2020), 研究区 As、Cu

和Cr含量与碳酸盐岩小流域相当,Pb、Ni和Zn含量与玄武岩小流域相当,除As和Pb外,各重金属含量均高于泥页岩小流域。典型煤矿区小流域沉积物重金属数据较少,因而收集了不同煤矿区周边表层土壤重金属数据,通过对比可知,研究区As、Cd和Pb含量与黔西、浙西和陕北典型煤矿区土壤含量差别不大,但远低于贵州兴仁煤矿区土壤;Hg含量均远低于其他煤矿区,Ni含量与其他煤矿区相当,而Cu、Cr和Zn均高于其他煤矿区。

3.2 表层沉积物重金属污染特征及生态风险评价

3.2.1 地累积指数法评价

工作区沉积物重金属地累积指数统计结果见表5和图2。沉积物重金属的污染程度排序为Cr>Cu>Cd>Mn>Zn>V>Ni>Hg>Pb>As,其中Cr的污染程度较高, I_{geo} 均值为1.00,主要为偏中度污染和轻度污染,其频率分别为51.35%和45.95%,仅1个采样点为无污染;Cu以轻度污染和偏中度污染为主,

I_{geo} 均值为0.64,其频率分别为64.68%和18.92%。Cd、Mn、Zn、V和Ni均以轻度污染为主,无污染次之,轻度污染频率分别为51.35%、67.57%、59.46%、62.16%、59.46%和51.35%。As、Pb和Hg以无污染为主,其频率分别为89.19%、97.3%和78.38%。仅有个别采样点中Cd、Cu、Hg、Mn和Zn出现了中度污染,但其频率均较低。

3.2.2 潜在生态风险指数法评价

沉积物重金属潜在生态风险指数评价结果见图3和图4。各重金属的单因子危害指数均值排序为: Cd>Hg>Cu>As>Ni>Cr>V>Pb>Mn>Zn,这与滇黔桂岩溶区河漫滩表层沉积土壤重金属潜在生态风险的排序相近(赵东杰和王学求,2020),Cd和Hg存在较大的潜在生态风险。其中Cd的潜在生态风险最高, E_r^i 为28.90~331.65,均值为70.11; Hg的潜在生态风险次之, E_r^i 为14.48~248.28,均值为52.66,两者单因子危害指数均达到了中等风险,个

| >5 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

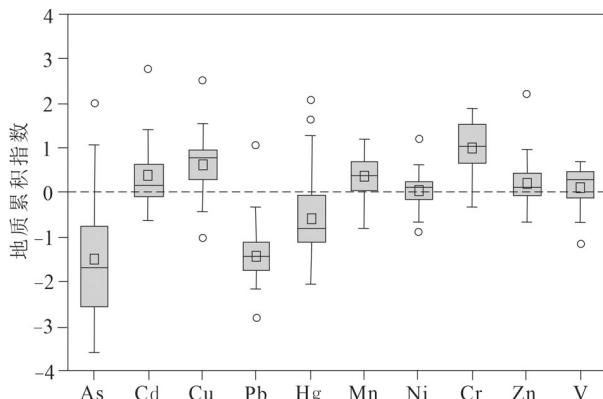

图2 研究区表层沉积物重金属地质累积指数箱线图
Fig.2 A box chart of heavy metal geological accumulation index of sediments in the surface sediments of the study area

别采样点达到了强和很强的风险,其他重金属的潜在生态风险指数均表现为低风险。从其污染程度看,Cd以轻度污染为主,Hg以无污染为主,但Cd和Hg的毒性系数较高,故而其潜在生态风险指数较强。而Cr和Cu的污染程度较高,但其毒性系数较低,故其潜在生态风险指数也较低。

RI值范围为93.83~647.14,均值为168.84,其中62.16%的采样点为低风险,32.43%的采样点为中等风险,有2个采样点(6和13)表现为强风险。Cd和Hg是最主要的生态风险贡献因子,两者对综合潜在生态风险指数的贡献率在57.02%~92.12%,均值为69.25%,需要引起相应的重视,这也与前人的研究结果一致。As在研究区的污染程度和潜在生态风险均较低,与庞文品等(2016)和吴先亮等(2018)的研究有所不同,这可能是因为黔西南是典型的高砷

煤矿区(丁振华等,2003),其煤层中砷含量较高,而研究区煤中砷含量较低导致的。

3.3 表层沉积物重金属来源解析

3.3.1 重金属相关性分析

根据重金属之间相关性的显著与否,可以判断它们是否具有相同或相似的来源(王丽等,2015;Barkett and Akün, 2018; Jiang and Guo, 2019)。由表6可知,As、Hg和Cd之间均显著相关($P<0.01$),As-Hg、As-Cd和Hg-Cd相关系数分别为0.76、0.46和0.43,表明三者可能有共同的来源或相似的传播途径;Pb和As呈显著相关($P<0.01$),但Pb和Hg、Cd相关性均较低,说明Pb来源较为复杂。Mn、Ni和V之间均显著相关($P<0.01$),Mn-Ni、Mn-V和Ni-V相关系数分别为0.80、0.59和0.60,说明它们之间具有相似的来源。Zn和Cu显著相关($P<0.01$),相关系数为0.85,Zn和Ni也显示一定的相关性,相关系数0.38($P<0.05$)。Cr和V弱相关,相关系数0.38($P<0.05$),和Ni也有一定相关性,相关系数0.28,和其他元素相关性均较低,且表现为负相关关系。有研究表明(卢瑛等,2004),Mn、Ni、V和Cr为亲铁元素,Cu和Zn为亲硫元素,同类元素在表生地球化学上具有一定共性,因而具有显著相关性。

3.3.2 重金属主成分和聚类分析

主成分分析是一种通过降维技术把多个变量化为少数几个主成分的多元统计分析方法,常用于研究沉积物中重金属污染情况(刘总堂,2010;邓渠成等,2017)。聚类分析可以把相似程度较高的指标聚合为一类,其结果可以用树状图直观地表示

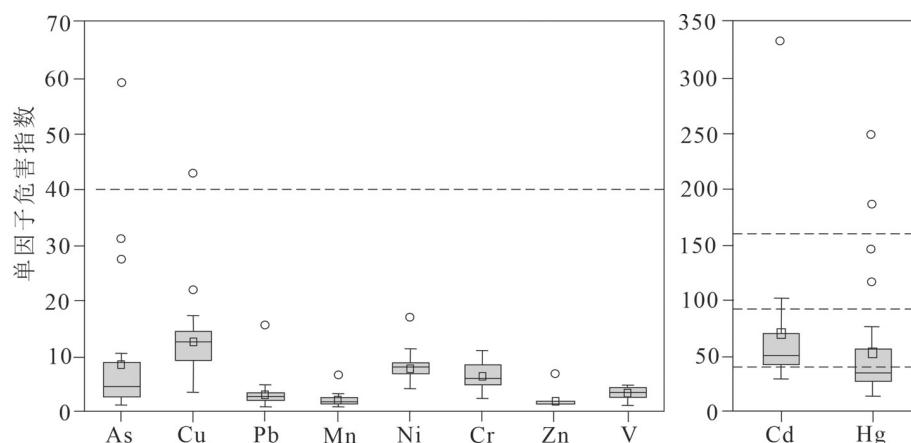

图3 研究区沉积物重金属生态风险评价结果
Fig.3 Ecological risk assessment results of heavy metals in sediments of the study area

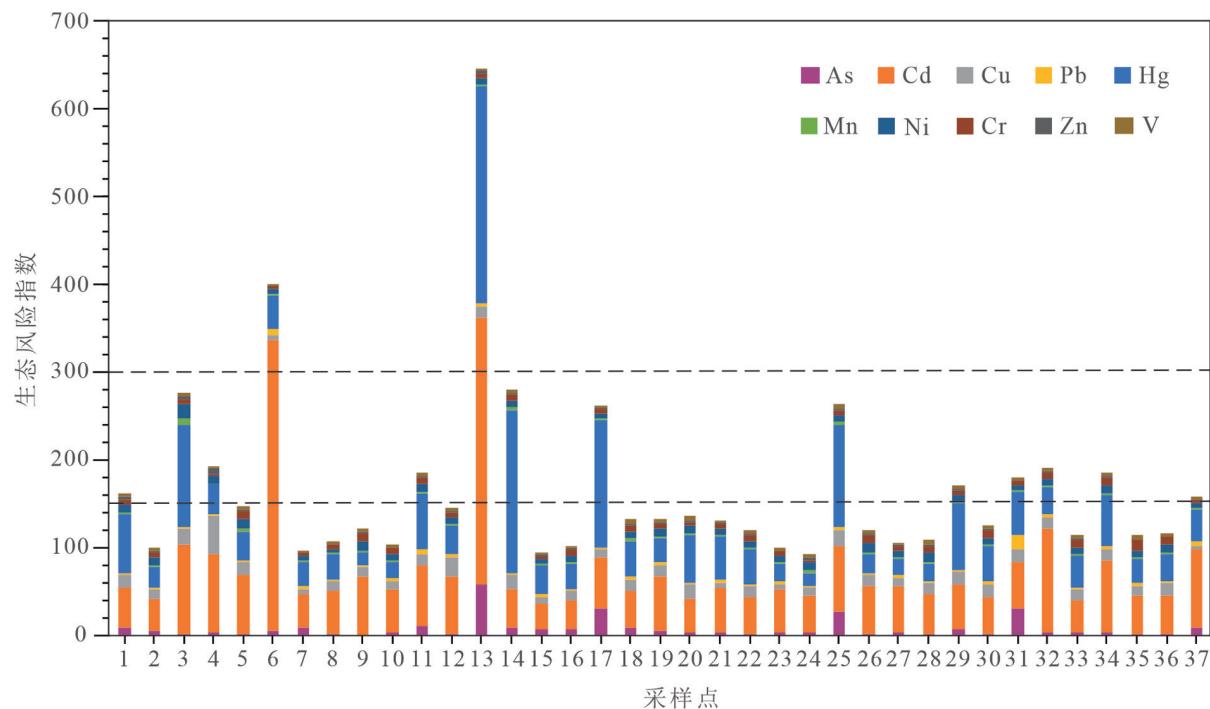

图4 研究区各采样点综合生态风险指数
Fig.4 Integrated ecological risk index of each sampling point in the study area

(代俊鸽等, 2015)。通过两种方法的结合, 可以更准确地识别沉积物中重金属的来源(张兆永等, 2015)。本文运用SPSS软件, 在经方差极大正交旋转后, 提取特征值大于1的6个公因子, 累积贡献率为93.91%(表7); 同时, 选用离差平方和(ward)算法和欧式距离进行R型聚类分组(袁建飞等, 2016), 得到聚类分析结果(图5), 在距离为5时, 将重金属元素划分为6类, 与主成分分析结果相对应。

主成分F1对总方差的贡献率为23.05%, 主要载荷为Mn、Ni和V, 三者之间均显著相关, 且变异

程度较低, 在空间上分布较均匀, 说明其人为来源较少(赵东杰和王学求, 2020), 主要受地质背景的控制。研究指出, V、Ni和Mn是土壤母质的特征元素(Post, 1999; 黄颖, 2018), 通常玄武岩发育的土壤中V、Ni和Mn的含量较高, 如中国南部地区玄武岩风化的砖红壤中V、Ni和Mn含量分别为243.0、224.4和1960 mg/kg, 且V和Ni含量与土壤Mn含量呈极显著或显著的正相关(汪金舫和刘铮, 1994)。中国东部玄武岩土壤中也同样具有较高含量的V、Ni和Mn(陈静生等, 1999), 王乔林等(2021)的研究

表6 研究区沉积物重金属含量相关关系
Table 6 Correlation coefficients between major ions of the study area

| | As | Cd | Cu | Pb | Hg | Mn | Ni | Cr | Zn | V |
|----|--------|--------|--------|--------|-------|--------|--------|-------|-------|---|

也指出滇西地区土壤中高含量的Ni主要来源于该区火山岩等成土母岩,因此认为F1主要受到玄武岩风化成土的影响。主成分F4对总方差的贡献率为11.88%,主要载荷为Cr,变异程度也较低。有研究(朱青青和王中良,2012)指出,中国水系沉积物中Cr多来源于自然风化过程,尤其在西南地区,三叠系飞仙关组碎屑岩重矿物中含有大量碎屑铬尖晶石(张英利等,2016;张衡等,2019),致使其土壤和沉积物中相对富集Cr,因而具有较高的背景值(肖高强等,2021);瞿书逸(2020)研究发现碳酸盐小流域沉积物中Cr含量较高,与研究区沉积物中的含量相当,因此认为研究区沉积物中Cr主要来源于碳酸盐岩和碎屑岩的风化过程。同时,F1和F4在聚类分析中可以归为同一类,具有一定相似性,因此F1和F4代表了沉积物重金属的自然来源,属于自然因子。

主成分F2贡献率为16.58%,主要载荷为Cu和Zn。Cu和Zn变异系数分别为49.59%和54.88%,属高度变异。贺灵等(2021)研究指出,中国西南Cu、Ni、Zn和Cd的高含量区域受峨眉山玄武岩控制,肖高强等(2021)也指出滇东典型地区土壤中的高Cu和Zn含量主要与峨眉山玄武岩和煤系地层有关。唐瑞玲等(2020)也发现云南宣威某地土壤中Cu高含量区域主要分布于玄武岩出露区。工作区出露大范围玄武岩,Cu和Zn的高值点多分布于靠近玄武岩及其周边的区域,因此F2可能受到了玄武岩风化的影响。但同时,研究区农业活动较发达,河流

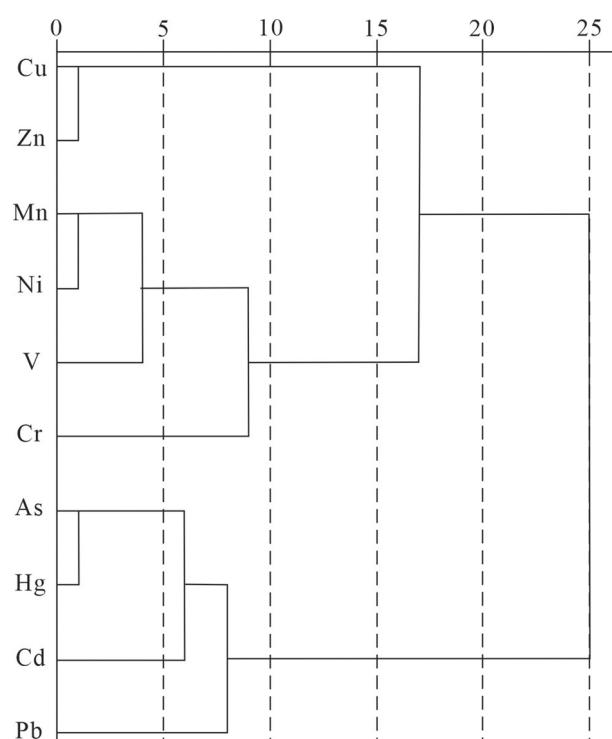

图5 沉积物重金属聚类分析结果
Fig.5 Clustering tree of heavy metals in sediments

周边路网交错,煤炭工业发达,运煤车辆较多,前人研究表明Cu和Zn还受农业活动(如肥料、农药等)、工业活动(降尘)和交通排放等的影响(朱青青和王中良,2012;陈雅丽等,2019;张倩等,2020),因此研究区Cu和Zn可能还有部分来自燃煤、交通和农业

活动等,综合认为主成分F2代表了自然来源和人为来源的综合影响。

主成分F3贡献率为18.24%,主要载荷为As和Hg;F5和F6贡献率分别为10.8%和10.69%,主要载荷分别为Pb和Cd,四者在沉积物中的含量均低,但都呈高度变异($72.23\% < C_v < 135.61\%$),表明受人类活动影响较强。由表6可知,As、Hg和Cd之间显著相关,尤其As和Hg相关系数达0.76($P < 0.01$)。研究区为重要的煤炭工业区,原煤产量高,煤炭洗选加工产业也发达,煤也是当地的生活生产的主要能源。研究指出,As、Hg、Pb和Cd是中国燃煤大气排放的主要重金属(高炜,2013;杨子鹏,2020),尤其Hg一般被当作煤炭燃烧的指示元素(Streets et al., 2005;陈雅丽等,2019),如范明毅等(2016)认为煤炭燃烧是毕节金沙电厂周边土壤Hg重要来源。有大量研究表明,工业废水、煤的燃烧均会向自然界释放大量As、Cd和Hg等重金属元素(朱青青和王中良,2012;温泉等,2020;赵东杰和王学求,2020),研究也表明滇黔地区煤矿周边容易存在As、Cd和Hg的污染(庞文品等,2006;吴先亮等,2018),与本次研究基本一致,因此认为F3主要代表了燃煤等煤炭工业对重金属的贡献。

但是,F5和F6主成分表明,Pb和Cd还有其他重要的来源。研究区沉积物中Pb含量低于云南省土壤背景值,与中国水系沉积物元素丰度值相当(表4)。通常认为Pb是交通尘的标示性元素(郭锋等,2013;王增辉,2020)。邵莉等(2012)在梳理中国交通源重金属污染情况时指出,含铅汽油的使用、汽车轮轴轴承摩擦和制动衬面摩擦均会释放出Pb,且重型车释放量是轻型车的5~6倍。工作区道路多位于河流沿线,大型运煤车辆较多,因此认为F5主要代表了道路交通的影响。滇东地区是典型的土壤Cd高背景值区域(李丽辉和王宝禄,2008;王宇等,2012),碳酸盐岩、玄武岩和炭质页岩等都是造成土壤高Cd背景的重要岩石类型(夏学齐等,2022),尤其碳酸盐岩风化成土是土壤和沉积物中Cd富集的主要来源(罗慧,2018)。同时,工农业生产活动也是其重要来源之一(Barcellos and Lacerda, 1994;骆永明,2009),施用化肥、农药和地膜等农业生产活动可能会导致土壤和沉积物中Cd含量增高或污染(Chien et al., 2009),尤其磷肥中有相当高的

Cd含量,也加重了土壤和沉积物中的Cd浓度(龙家寰等,2014)。因此,认为F6代表了自然背景和农业活动的共同影响。综合来看,F3、F5和F6受到了燃煤等煤炭工业活动、道路交通和农业活动等的影响,在聚类分析中可归为一类,代表了人类活动对重金属的影响,属于人为因子。

4 结 论

(1)研究区沉积物中除As和Pb外,其余重金属均超过了云南省土壤背景值,但仅Cu的平均含量超过风险筛选值。各重金属变异系数大小依次为As>Hg>Cd>Pb>Zn>Cu>Mn>Cr>Ni>V,其中Cr、Ni和V为中等变异,其余重金属均为高度变异。

(2)地累积指数法评价显示重金属污染程度为Cr>Cu>Cd>Mn>Zn>V>Ni>Hg>Pb>As,其中Cr主要为偏中度污染,Cu、Cd、Mn、Zn、V和Ni主要为轻度污染,As、Pb和Hg主要为无污染。潜在生态风险指数法评价表明研究区沉积物总体呈低风险—中等风险,Cd和Hg是最主要的生态风险因子,均表现为中等风险,其余重金属的生态风险则较低。

(3)相关性分析、主成分分析和聚类分析结果表明,研究区沉积物重金属受到人类活动和自然背景的双重控制,其中Mn、Ni、V和Cr主要为自然来源,受成土母岩风化的控制;As、Hg、Cd和Pb主要为人为来源,受燃煤等煤炭工业活动、交通排放和农业活动的影响;而Cu和Zn则受到自然来源和人为来源的综合控制。
