摘要: 煤型铀主要是指赋存于煤层的铀, 一般以煤中铀含量大于或等于 $40 \mu\text{g/g}$ 为煤型铀资源界定标准。为总结云南省煤中铀含量特征, 查明煤型铀资源分布规律。通过系统查阅 196 份煤田勘查报告, 筛查出 12 个煤矿中 109 口钻孔的至少 208 个煤中铀含量数据, 结合前人数据共整理出 23 个煤矿中的至少 1044 个煤中铀含量数据, 统计分析显示: (1) 煤中铀含量差异显著, 分布极为不均; (2) 峨山塔甸三叠系无烟煤中平均铀含量为 $27.6 \mu\text{g/g}$, 系国内新发现的又一罕见的无烟煤型铀富集区; (3) 澜西等航、临沧勐旺—帮卖、建水甸尾、弥勒跨竹、蒙自南部的新近系褐煤和文山邱砚煤田的二叠系贫煤、新近系长焰煤, 共 6 个地区煤中铀含量达到煤型铀资源界定标准, 尤以临沧盆地群和邱砚煤田最具煤—铀及多金属勘探开发价值。初步分析认为煤中铀含量受煤阶影响有限, 铀源供给才是铀富集并成矿的先决条件。

铀及其放射性同位素是军工和核电产业不可或缺的战略性矿产资源, 我国铀矿床最大的特点是以花岗岩型、火山岩型、砂岩型和碳硅泥岩型为主, 被称为中国“四大类型”的铀矿, 占探明资源量的 92.2%^[1]。煤中铀的品位一般不高, 自然界大多数煤中含铀量不超过 $10 \mu\text{g/g}$ ^[2], 中国煤中的铀平均含量为 $2.43 \mu\text{g/g}$ ^[3], 但由于煤层多、厚度大, 面积广, 故煤中铀的远景储量可观。尤其是铀在燃烧后富集于其灰分中, 含铀煤既可作工业燃料, 铀又可从灰分中作为副产品提取, 从而大大提高了矿床的工业意义^[4]。国内核工业系统在 1960 年前后开展了煤(岩)型铀矿的普查及专项研究, 按硬岩型铀矿一般工业品味指标(边界品位 0.03%, 最低工业品位 0.05%), 发现了塔里木盆地的萨瓦布其、伊犁盆地的达拉地、蒙其古尔和库米什盆地的苏克苏克等煤(岩)型铀矿床^[5]。后有学者指出煤中铀含量超过 $200 \mu\text{g/g}$ 就可作为共、伴生矿产进行开采^[6-7], 当煤中铀含量达到大于或等于 $40 \mu\text{g/g}$ 时, 即具有潜在的铀矿资源储备价值, 可回收利用^[8-9]。

作为煤炭资源大省之一的云南, 自 1992 年来虽陆续有学者对该区煤矿中铀含量进行过报道^[10-11], 但由于云南煤田系统数十年间勘查生产积累的最为详尽的成果资料尚未曾盘活, 致使学界对区内煤型铀资源特征依然难以全面把握。为此, 笔者以 2014 年实施至今的西南地区“煤铀兼探”项目为依托^[12], 系统开展了云南省煤田勘查资料的搜集整理与二次开发利用, 重点发掘成果报告中的煤中铀含量数据, 拟通过数据统计分析, 总结煤中铀含量特征, 查明煤型铀资源分布规律, 为后期勘探开发提供依据。

1 云南省区域地质和煤炭资源概况

云南以金沙江—红河断裂为界, 东为华南板块, 西为甘青藏板块。印支期—燕山中期, 古、中特提斯海域分别沿金沙江—哀牢山缝合带、碧土—昌宁—孟连缝合带及班公湖—怒江缝合带闭合, 云南全境上升成陆, 结束了海侵历史。新生代中始新世末期, 印度板块向北俯冲, 沿雅鲁藏

布江缝合带与冈底斯—腾冲中间板块碰撞，新特提斯洋消亡，印度次大陆与古欧亚大陆连为一体^[13]。云南煤田地质调查始于1950年，截至2009年底，对主要含煤区的大规模区域找煤已基本完成。云南省煤炭资源总量约 $751\times10^8\text{ t}$ ，在中国南方(华中、华南、西南及港澳台地区)15个省级行政区中仅次于贵州，居第二位。成煤期有9个，早石炭世、中二叠世、晚二叠世、晚三叠世

和新近纪这5个时期形成可开采利用的煤炭资源。褐煤资源量约占全省保有资源储量的53.23%，烟煤占26.89%，无烟煤占19.88%。赋煤单元以金沙江—哀牢山断裂带为界分为华南赋煤区和滇藏赋煤区2个I级构造单元，进一步划分出腾冲—潞西、保山—临沧、兰坪—普洱、华坪—楚雄、昆明—建水、昭通—曲靖及蒙自—文山7个II级赋煤带^[14](图1)。

Fig.1 Distribution of coalfield-type resource in Yunnan Province (modify after[14])

2 云南省煤中铀含量特征与煤型铀资源分布规律

云南省煤田系统自1950~2009年共完成勘探报告(含详终、普终)165件、详查报告149件、普查报告77件^[14]。通过系统查阅196份上述各类煤田勘查报告，发掘出12个煤矿中109口钻孔的至少208个煤中铀含量数据，结合前人已发表数据，共整理出7个赋煤带15个煤田(盆地)23个煤矿中的至少1044个煤中铀含量数据(表1)，数据构成从煤类看，褐煤占绝大多数(>712件)，

其次是烟煤(276件)，还有少量无烟煤样(56件)；从时代看，以新近系煤样占绝大多数(>931件)，其次是三叠系(65件)和二叠系(48件)煤样。经过统计分析发现云南省煤中铀含量具有以下特点。

2.1 煤中铀含量差异显著，分布极为不均

单个煤样以临沧勐腊东煤矿最高，达 $2522\text{ }\mu\text{g/g}$ ，平均值以建水甸尾煤矿最高， $\bar{U}>500\text{ }\mu\text{g/g}$ 。在景谷、普洱、曲靖恩洪和砚山干河煤矿中均检测到 $0.1\text{ }\mu\text{g/g}$ 的单个煤样最低值，平均值以曲靖恩洪煤矿最低，为 $0.2\text{ }\mu\text{g/g}$ 。即使在同一

地区同时代同类型煤中铀含量依然高低相差悬殊, 例如: 建水盆地新近系褐煤单个煤样最高

为 $1100 \mu\text{g/g}$, 最低为 $2.8 \mu\text{g/g}$, 平均值最高大于 $500 \mu\text{g/g}$, 最低仅为 $10.5 \mu\text{g/g}$ (表 1)。

2.2 无烟煤中新发现铀富集

以往研究发现煤型铀主要富集在褐煤、长焰煤中^[9~10], 仅在广东梅县童子岩组无烟煤(铀含量 $0\sim 23 \mu\text{g/g}$), 湖南涟邵煤田芦茅江测水组无烟煤(铀含量 $10\sim 90 \mu\text{g/g}$)和重庆松藻龙潭组无烟煤(铀含量 $5\sim 108 \mu\text{g/g}$)中报道过铀富集^[6], 表 1 数据显示峨山塔甸煤矿三叠系无烟煤中铀含量在 $7.9\sim 68.3 \mu\text{g/g}$, 平均铀含量达 $27.6 \mu\text{g/g}$, 为中国煤平均铀含量($2.43 \mu\text{g/g}$)^[3]和世界煤平均铀含量($2.4 \mu\text{g/g}$)^[21]的约 11 倍。峨山塔甸煤矿是本次工作新发现的又一罕见的无烟煤型铀富集区。

2.3 云南煤型铀资源分布及其经济可采性初步评价

按煤中铀含量大于或等于 $40 \mu\text{g/g}$ 的设定标准, 23 个煤矿中仅潞西等航($\bar{U}=294.9 \mu\text{g/g}$)、临沧勐旺—帮卖($\bar{U}=54.8\sim 242.5 \mu\text{g/g}$)、建水甸尾($\bar{U}>306 \mu\text{g/g}$)、弥勒跨竹($\bar{U}=118.6 \mu\text{g/g}$)、蒙自南部($\bar{U}=51.5 \mu\text{g/g}$)的新近系褐煤和文山邱砚煤田的二叠系贫煤($\bar{U}=155 \mu\text{g/g}$)、新近系长焰煤($\bar{U}=55.7\sim 101.1 \mu\text{g/g}$), 共 6 个地区煤中铀含量达到煤型铀矿的界定标准, 腾冲—潞西、兰坪—普洱和华坪—楚雄 3 个赋煤带暂未发现煤型铀资源。从煤

层时代和煤类来看,除邱砚煤田有8件二叠系的贫煤样品富铀外,其余至少280件煤样显示铀主要富集在新近系褐煤(>148件)和长焰煤(132件)中,三叠系煤中未发现煤型铀矿。从经济可采性来分析,6个地区中临沧盆地群不仅煤中富铀,砂岩中也富集铀矿,业已探明个9个中小型砂岩型铀矿^[22],更为重要的是煤中还产出超大型锗矿,矿石类型以锗煤型为主,锗主要以有机化合物形式存在于镜质组中,矿床具有埋藏浅、品位富、规模大和易采、治等特点^[23]。临沧盆地群这一煤—铀—锗多金属富集的天然优势使其极具商业勘探开采价值。另外,邱砚煤田煤型铀矿分布面积为6区之最,且新近系和二叠系两套煤中铀均达到界定标准不仅如此,前人发现二叠系贫煤中U-Cr-Mo-V-Re均超常富集^[19-20],具煤型铀分布面积广、层位多且煤—铀及多金属富集的特点,同样应引起勘探工作高度重视。

3 对铀成矿过程研究的启示

一般认为,煤中铀的含量与煤阶负相关,煤阶的影响主要表现为富铀煤多为褐煤和长焰煤,烟煤富铀程度相对有限。这主要是因为褐煤和长焰煤的结构较为疏松,孔隙较为发育,有助于吸附作用的发生。更为重要的是,褐煤和长焰煤中的腐植酸对铀酰离子具有明显的络合和还原作用,而在较高变质程度的煤中,腐植酸则发生降解和消失^[9-10]。但与上述认识不符的是:云南邱砚煤田二叠系贫煤平均铀含量155 μg/g,贵州贵定煤田二叠系烟煤平均铀含量为211 μg/g^[24],新疆伊犁煤田早—中侏罗烟煤平均铀含量320 μg/g,重庆磨心坡煤田二叠系烟煤平均铀含量376 μg/g,湖南辰溪煤矿二叠系肥煤铀含量高达440 μg/g^[6],上文所述的广东梅县、湖南涟邵、重庆松藻和峨山塔甸无烟煤中也存在铀富集,以上客观现象指示铀富集并不局限在低阶煤中,高阶煤也可以富集铀,煤中铀含量可能会受煤阶影响,但程度有限。加上表1显示的同时代同类型煤中铀含量差异显著,分布极为不均的特点,共同表明:从铀成矿“源—运—聚”过程来看,聚集条件(煤类)并非铀富集的主控因素,铀源供给才是铀富集并成矿的先决条件。

4 结 论

(1) 云南省煤中铀含量差异显著,分布极为

不均。峨山塔甸三叠系无烟煤中新发现铀富集。

(2) 云南煤型铀矿主要分布于潞西等矿、临沧勐旺—帮卖、建水甸尾、弥勒跨竹、蒙自南部新近系煤矿和文山邱砚二叠系、新近系煤田,尤以临沧盆地群和邱砚煤田最具煤—铀及多金属勘探开发价值。

(3) 铀可以在不同煤阶的煤中富集,煤中铀富集受煤阶的影响有限,铀源才是关键因素。

Abstract: During the Meishucun period of the Early Cambrian, a large-scale phosphorus formation event occurred on the Upper Yangtze platform. As the product of this event, the sedimentary environment and formation mechanism of phosphorite remains elusive. In order to better understand the sedimentary environment and formation mechanism of phosphorite enrichment, we investigated the geochemical characteristics of phosphorite in Maidiping Formation of Lower Cambrian in Huangjiaping area of Mabian County. The results show that: Σ REE has significant positive correlation with P_2O_5 , and $(La/Yb)_N$ and $(La/Sm)_N$ ratio are $0.98 \sim 1.61$ and $0.93 \sim 1.39$, indicating that REE enrichment is affected by early diagenetic adsorption, and the phosphorite retains the original fractionation characteristics of REE. Obvious negative Ce anomalies (average Ce/Ce^* is 0.44) and the absence of frambooid pyrite in the phosphorite indicating that the phosphorite were deposited under oxic/dysoxic conditions. The high Y/Ho ratio (mean 65) is consistent with the Y/Ho ratio of modern oxygen-containing seawater, indicating that phosphorite is derived from the original oxic seawater. The weak negative Eu anomaly (Eu/Eu^* mean value is 0.9) indicates that the formation of phosphorite is not affected by hydrothermal activity. The REE distribution pattern is “hat type”, indicating that the formation of phosphorite is controlled by Fe-redox pump at sea-sediment interface. In combination with the above findings and combined with the highly stratified redox ocean structure and the intensive upwelling in the early Cambrian, the phosphate released during the redox of FeOOH was transported into the shallow water. In the shallow underground burial, phosphate is enriched by biodegradation and reductive release of FeOOH, and finally phosphate and Ca^{2+} are combined to form apatite, which is continuously enriched and ore-forming.

standard. In order to summarize the characteristics of uranium content in coal in Yunnan Province and find out the distribution law of coal-type uranium resources. Through systematic review of 196 coal field exploration reports, the uranium content data of at least 208 coals of 109 boreholes in 12 coal mines were screened out. Combined with previous data, the uranium content data of at least 1044 coals in 23 coal mines were sorted out. Our statistical analysis shows that: (1) Uranium content in coal varies significantly and its distribution is extremely uneven. (2) The average uranium content in Triassic anthracite in Eshan Tadian is $27.6 \mu\text{g/g}$, which is another rare anthracite uranium enrichment area newly discovered in China. (3) The Neogene lignite of Denggang coal mine in Luxi basin, Mengwang-Bangmai coal mine in Lincang basin, Dianwei coal mine in Jianshui, Kuazhu coal mine in Mile basin and southern Mengzi basin, with Permian lean coal and Neogene long flame coal in Qiuyan coal field in Wenshan, a total of six areas of uranium content in coal reach to the define standard of coal-type uranium deposits, especially in the Lincang basin group and Qiuyan coalfield own the most value in coal-uranium and polymetallic exploration and development. The preliminary analysis shows that uranium content in coal is not limited by coal rank and uranium source supply is the prerequisite for uranium enrichment and mineralization.
